

HTTP Server configuration

The information on this page refers to License Statistics v6.6 or newer, which introduced the License Statistics Manager, a tool that replaces direct editing of the `xflicstat.cfg` configuration file for Windows installations. If you are running an older version of License Statistics, see [documentation for previous versions](#).

License Statistics configuration includes a port setting ("WEBSERVER_PORT" in the "HTTP" section of the `xflicstat.cfg` file, or "Port" in the [License Statistics Manager's](#) Webserver tab) for the HTTP server used for viewing License Statistics output. The port setting defaults to 80 when SSL is disabled, or 443 when SSL is enabled. You should check the log file to ensure that the port is available for your site, and change this setting if needed. For more information about SSL configuration, see [Enabling Tomcat SSL](#). For common problems with configuring web server ports and steps to resolve them, see [Configuring web server ports](#).

The HTTP server configuration also includes a setting for the base URL, which is the address used to access the License Statistics UI using a browser.
